Required Exercise 1 [2]

1. Type `\(726 \equiv 23 \pmod{19}\)` to get $726 \equiv 23 \pmod{19}$.
2. Prove or disprove that $726 \equiv 23 \pmod{19}$.

Proof. We start by stating the definition. $726 \equiv 23 \pmod{19}$ is the same as saying $19 \mid (726 - 23)$. Simplifying the expression, we get $19 \mid (703)$.

We see that $19 \times 37 = 703$. Therefore, $726 \equiv 23 \pmod{19}$. □

Required Exercise 2 [4]

Suppose $a \equiv a' \pmod{m}$ and $b \equiv b' \pmod{m}$. Prove the following:

1. $a + b \equiv a' + b' \pmod{m}$.

Proof. We begin with by defining $a \equiv a' \pmod{m}$ as $m \mid (a - a')$. Similarly, $m \mid (b - b')$. Following from these definitions, we write:

$$a - a' = m \times k_1 \tag{1}$$

$$b - b' = m \times k_2 \tag{2}$$

We can add equations 1 and 2 together to get $a + b - a' - b' = m \times k_1 + m \times k_2$.

With some factoring, we get $(a + b) - (a' + b') = m(k_1 + k_2)$.

By definition, we find that $m \mid (a + b) - (a' + b')$, and thus $a + b \equiv a' + b' \pmod{m}$. □

2. $a - b \equiv a' - b' \pmod{m}$.

Proof. Following from Proof 1, we can instead subtract equation 1 and 2 to get $a - b - a' + b' = m \times k_1 - m \times k_2$.

With some factoring, we get $(a - b) - (a' - b') = m(k_1 - k_2)$.

By definition, we find that $m \mid (a - b) - (a' - b')$, and thus $a - b \equiv a' - b' \pmod{m}$. □

3. $a \times b \equiv a' \times b' \pmod{m}$.

Following from equation 1, we get

$$a = a' + m \times k_1. \tag{3}$$

Similarly, from equation 2, we get

$$b = b' + m \times k_2. \tag{4}$$

By multiplying equations 3 and 4, we get $a \times b = (a' + m \times k_1)(b' + m \times k_2)$.

From now on, I will omit the \times symbol.

By distributing, we get

$$ab = a'b' + a'mk_2 + b'mk_1 + m^2k_1k_2.$$

We can factor out m to find

$$ab = a'b' + m(a'k_2 + b'k_1 + mk_1k_2).$$

We can subtract $a'b'$ from both sides to find

$$ab - a'b' = m(a'k_2 + b'k_1 + mk_1k_2).$$

By definition, we see that $m \mid (ab - a'b')$, and, by extension, $ab \equiv a'b' \pmod{m}$.

Required Exercise 3 [4]

Problem 8.2 Give two reasons why ' $f : \mathbb{R} \rightarrow \mathbb{R}$ where $f(x) = \pm\sqrt{x}$ ' is not a function.

1. The first reason that f is not a function is because of an invalid domain. The function *should* map all reals (domain) to a subset of the reals (codomain), but negative values actually map to imaginary numbers.
2. The second reason that f is not a function is because of the "non-unique" output. One of the requirements for a function is that one value from the domain maps to one and only one value from the codomain. However, f maps a single value x to two values due to the \pm .

Choice Exercise 4 [4]

2. Show that every positive integer is a sum of one or more numbers of the form 2^r3^s , where r and s are nonnegative integers and no summand divides another. (For example, $23 = 9 + 8 + 6$).

Proof. We begin by showing that such summations exist for small n . This will act as a base case for an inductive step later.

$n = 0$ Trivially true.

$n = 1$ $1 = 2^03^0$.

Now, we create the inductive hypothesis that all nonnegative integers strictly less than n have such summation.

If n is even, we can construct a valid summation by noticing that, from our inductive hypothesis, $\frac{n}{2}$ has a valid summation $\sum_{i=1}^k 2^{r_i}3^{s_i}$. Since none of these summands divide any other summand, multiplying all summands by 2 also creates a set of summands such that no summand divides another.

If n is odd, we can also construct a valid summation by picking a value 3^t that is the biggest power of 3 that is less than or equal to n . Our proposition is trivially true if $n = 3^t$. Otherwise, we must find a value $m = n - 3^t$.

Since n and 3^t are both odd, m must be even. Also notice that $m < n$. Thus, there must exist a valid summation $m = \sum_{j=1}^k 2^{r_j}3^{s_j}$ where all $r_j \geq 1$.

Since all summands of m are even, 3^t can not be divisible by any of the summands of m . Also, since $r_j \geq 1$, there must not be any summand where $s_j \geq t$ because if such summand existed, we would find at least a value of $n = 3^t + 2(3^t) = 3^{t+1}$. This is a contradiction, since we defined 3^t as the largest power of 3 less than or equal to n .

Thus, $n = \sum 2^r3^s$ where no summand divides another for all nonnegative integers n . \square

Choice Exercise 8 [6]
